## DNA, CONSTRUCTS, CELLS AND PLANTS DERIVED THEREFROM

This application relates to novel DNA constructs, plant cells containing them and plants derived therefrom. In particular it involves the use of recombinant DNA technology to control gene expression in plants.

In work leading to the present invention we have identified a gene which expresses an enzyme involved in the ripening of tomatoes. This gene has been cloned and characterised. We have now shown that it is involved in carotenoid synthesis. The gene in question is encoded (almost completely) in the clone pTOM5, disclosed by Ray et al (Nucleic Acids Research, 15, 10587, 1989).

The carotenoid biosynthesis pathway is shown in outline in Figure 4 hereof. We believe that the pTOM5 gene is involved in the step or steps of the pathway between geranylgeranyl pyrophosphate and phytoene. Among the products produced by this branch of the pathway are carotenes, lutein, xanthophylls, and pigments such as lycopene. The present invention proposes to modify the synthesis of such compounds in plants.

According to the present invention we provide DNA constructs comprising a DNA sequence homologous to some or all of the gene encoded by the clone pTOM5, preceded by a transcriptional initiation region operative in plants, so that the construct can generate mRNA in plant cells. We further provide a process for modifying the production of carotenoids in plants by transforming such plants

**SUBSTITUTE SHEET**

- 2 -

with constructs according to the present invention. We further provide a process for modifying the production of carotenoids in plants by transforming such plants with DNA adapted to modify carotenoid biosynthesis and growing such transformed plants or their descendants to produce plant parts (for example leaves, petals or fruit) of modified carotenoid content. Suitable DNA comprises, inter alia, constructs according to the present invention, but other similar constructs affecting other parts of the carotenoid pathway may also be used. Such constructs may be adapted to enhance the production of carotenoids (for example lycopene) or inhibit such production by the plant.

As is well known, a cell manufactures protein by transcribing the DNA of the gene for that protein to produce messenger RNA (mRNA), which is then processed (eg by the removal of introns) and finally translated by ribosomes into protein. This process may be inhibited by the presence in the cell of "antisense RNA". By this term is meant an RNA sequence which is complementary to a sequence of bases in the mRNA in question: complementary in the sense that each base (or the majority of bases) in the antisense sequence (read in the 3' to 5' sense) is capable of pairing with the corresponding base (G with C, A with U) in the mRNA sequence read in the 5' to 3' sense. It is believed that this inhibition takes place by formation of a complex between the two complementary strands of RNA, preventing the formation of protein. How this works is uncertain: the complex may interfere with further transcription, processing, transport or translation, or degrade the mRNA, or have more than one of these effects. Such antisense RNA may be produced in the cell by transformation with an

**SUBSTITUTE SHEET**

- 3 -

appropriate DNA construct arranged to transcribe backwards part of the coding strand (as opposed to the template strand) of the relevant gene (or of a DNA sequence showing substantial homology therewith).

The use of this technology to downregulate the expression of specific plant genes has been described, for example in European Patent publication no 271988 to ICI (corresponding to US serial 119614). Reduction of gene expression has led to a change in the phenotype of the plant: either at the level of gross visible phenotypic difference e.g. lack of anthocyanin production in flower petals of petunia leading to colourless instead of coloured petals (van der Krol et al, Nature, 333, 866-869, 1988); or at a more subtle biochemical level e.g. change in the amount of polygalacturonase and reduction in depolymerisation of pectins during tomato fruit ripening (Smith et al, Nature, 334, 724-726, 1988; Smith et al., Plant Molecular Biology, 14, 369-379, 1990). Thus antisense RNA has been proven to be useful in achieving downregulation of gene expression in plants.

In a further aspect, the present invention provides DNA constructs comprising a transcriptional initiation region operative in plants positioned for transcription of a DNA sequence encoding RNA complementary to a sequence of bases showing substantial homology to an mRNA encoding the enzyme produced by the gene in pTOM5. The invention also includes plant cells containing constructs according to the invention; plants derived therefrom showing modified characteristics, e.g. fruit colour; and fruit and seeds of such plants.

SUBSTITUTE SHEET

- 4 -

The constructs of the invention may be inserted into plants to regulate the production of the pTOM5 enzyme. Depending on the nature of the construct, the production of the enzyme may be increased, or reduced, either throughout or at particular stages in the life of the plant. Generally, as would be expected, production of the enzyme is enhanced only by constructs which contain DNA homologous to the substantially complete gene. What is more surprising is that constructs containing an incomplete DNA sequence substantially shorter than that corresponding to the complete gene generally inhibit the expression of the enzyme, whether they are arranged to express sense or antisense RNA.

Further evidence for the function of the pTOM5 gene in the carotenoid pathway (see Figure 4) is a significant degree of homology (27% identity; 17% similarity) between the polypeptide predicted from the translation of the pTOM5 sequence and the protein encoded by the crtB gene from Rhodobacter capsulatus, a gram-negative purple non-sulphur bacterium. The crtB gene product catalyses the tail to tail dimerisation of geranylgeranyl pyrophosphate to form prephytoene pyrophosphate. This enzyme (prephytoene synthetase) is the point of divergence of carotenoid biosynthesis from other isoprenoid metabolism. Further, an enzyme has been isolated from Capsicum annuum fruit chromoplasts which is believed to catalyse both the synthesis of prephytoene pyrophosphate and its subsequent conversion to phytoene. This enzyme has a molecular weight of 47,500, in close agreement with the predicted size of the pTOM5 protein (48,000).

As well as colour production, other important functions may be modified by the process of the

- 5 -

invention. Thus  $\beta$ -carotene (a precursor of Vitamin A) and other carotenoids are important to human health, and have been claimed to have a protective effect against certain diseases. Food plants may be modified by transformation with the constructs of the invention so that they have a higher content of such compounds: or other plants may be so modified, so that they can act as a source from which such compounds can be extracted. Carotenoids are also believed to have a role in protecting plants against high light intensity damage, so plants with a higher content of such compounds may be of value in combating the effects of any global climate change.

A further possible application of the invention is to control sporopollenin synthesis. This polymer is believed to be a product of carotenoid biosynthesis. Sporopollenin is important during pollen formation and maturation, particularly during the early stages of sporogenesis. Modification of expression of the pTOM5 gene according to the invention in the tapetum is expected to lead to interference in pollen formation, particularly through changing the formation, development or function of the tapetum. Thus inhibition of sporopollenin may be effected in all plants producing sporopollenin through a route involving carotenoids. Accordingly the invention may be used to inhibit the production of pollen in transformed plants. Plants so produced will be male-sterile, and will be useful in the commercial production of uniform hybrids. For this application it is important to use constructs containing promoters which are functional in the tapetum, for example the pollen promoter MFS 14. Not all constitutive promoters work in the tapetum

**SUBSTITUTE SHEET**

- 6 -

(for example, the CaMV 35S promoter does not).

The plants to which the present invention can be applied include commercially important fruit-bearing plants, in particular the tomato. In this way, plants can be generated which have modified colour due to promotion or inhibition of the pathways of carotenoid biosynthesis (and in particular of the pigment lycopene).

The invention may be used to promote or inhibit the production of the red colour associated with lycopene. Inhibition of this red colour in tomato fruit (eg by transformation with antisense constructs) gives fruit of an attractive shade of yellow (like certain peppers). Similar yellow tomatoes are known, but the present invention provides a means of transferring the trait into elite lines without a prolonged breeding programme which might alter other traits at the same time. Promotion of lycopene production may produce tomato fruit of a deeper red colour, which may appear more appetising to the consumer, particularly in the form of processed material such as pastes and soups. The invention may also be used to introduce a red colour into parts of plants other than the fruit. Promotion of lycopene may be brought about by inserting one or more functional copies of the gene cDNA, or of the full-length gene, under control of a promoter functional in plants. If lycopene is naturally expressed in the plant, the promoter may be selected to give a higher degree of expression than is given by the natural promoter.

Antisense DNA constructs according to the invention may be very short. They preferably comprise a homologous base sequence at least 10 bases in length. There is no theoretical upper limit to the base sequence - it may be as long as

**SUBSTITUTE SHEET**

- 7 -

the relevant mRNA produced by the cell - but for convenience it will generally be found suitable to use sequences between 100 and 2000 bases in length. The preparation of such constructs is described in more detail below.

The preferred DNA for use in the present invention is DNA derived from the clone pTOM5. The required DNA encoding antisense RNA can be obtained in several ways: by cutting with restriction enzymes an appropriate sequence of such DNA; by synthesising a DNA fragment using synthetic oligonucleotides which are annealed and then ligated together in such a way as to give suitable restriction sites at each end; by using synthetic oligonucleotides in a polymerase chain reaction (PCR) to generate the required fragment with suitable restriction sites at each end. The DNA is then cloned into a vector containing upstream promoter and downstream terminator sequences, the cloning being carried out so that the DNA sequence is inverted with respect to its orientation in the strand from which it was cut.

In new vectors expressing antisense RNA, the strand that was formerly the template strand becomes the coding strand, and vice versa. The new vector will thus encode RNA in a base sequence which is complementary to the sequence of pTOM5 mRNA. Thus the two RNA strands are complementary not only in their base sequence but also in their orientations (5' to 3').

As source of the DNA base sequence for transcription, it is convenient to use a cDNA clone such as pTOM5. The base sequence of pTOM5 is set out in Figure 1. This clone has been deposited at the National Collections of Industrial and Marine Bacteria, now at 23 St. Machar Drive, Aberdeen

**SUBSTITUTE SHEET**

- 8 -

AB2 1RY, Scotland, as a plasmid in E.coli, under the reference NCIB 40191, on 1 September 1989. Alternatively, a cDNA clone similar to pTOM5 may be obtained from the mRNA of ripening tomatoes by the method described by Slater et al, Plant Molecular Biology 5, 137-147, 1985. In this way may be obtained sequences coding for the whole, or substantially the whole, of the mRNA produced by pTOM5. Suitable lengths of the cDNA so obtained may be cut out for use by means of restriction enzymes.

As previously stated, the preferred source of antisense RNA for use in the present invention is DNA showing homology to the gene encoded by the clone pTOM5 (deposited at the NCIMB as 40191, see above). pTOM5 was derived from a cDNA library isolated from ripe tomato RNA (Slater et al Plant Molecular Biology 5, 137-147, 1985). Three other clones (pTOM45, pTOM91, pTOM104) from the same library cross-hybridise to pTOM5 and probably contain related sequences. pTOM5 has been characterised by hybrid select translation to encode a protein of approximately 48kD (Slater et al, Plant Molecular Biology 5, 137-147, 1985). DNA sequence analysis has demonstrated that the clone is 1600 bases long with an open reading frame encoding a polypeptide of 46.7kD.

We have shown that the mRNA for which pTOM5 codes is expressed in ripening tomato fruit. No expression could be detected in green fruit. pTOM5 is expressed most strongly at the full orange stage of ripening. The level of mRNA then declines in line with the general decline in biosynthetic capacity of the ripening fruit. Expression of pTOM5 mRNA could also be induced by exposing mature green fruit to exogenous ethylene. The expression

**SUBSTITUTE SHEET**

- 9 -

of pTOM5 is reduced in the Ripening inhibitor (rin) and Neverripe (Nr) tomato fruit ripening mutants which mature very slowly, and never achieve the full red colour associated with ordinary tomato fruit.

The genomic locations in the tomato of sequences homologous to pTOM5 have been identified using RFLP mapping: two loci, on chromosome 2 and chromosome 3 respectively, carry sequences homologous to pTOM5. It has also been shown by Southern blotting that the gene may be present as a small multigene family. Genomic clones representing two individual genes have been isolated and characterised by DNA sequence analysis. gTOM5 represents a gene with exon sequence identical to pTOM5. Clone F contains sequence similar, but not identical to pTOM5. Sequence and expression data suggest that Clone F encodes an untranscribed pseudogene.

Although there is a considerable body of information on the structure and expression of the pTOM5 gene family, the biochemical function of this clone has not hitherto been known.

An alternative source of DNA for the base sequence for transcription is a suitable gene encoding the pTOM5 enzyme. This gene may differ from the cDNA of pTOM5 in that introns may be present. The introns are not transcribed into mRNA (or, if so transcribed, are subsequently cut out). When using such a gene as the source of a partial base sequence for transcription it is possible to use either intron or exon regions.

A further way of obtaining a suitable DNA base sequence for transcription is to synthesise it ab initio from the appropriate bases, for example using Figure 1 as a guide.

**SUBSTITUTE SHEET**

- 10 -

Recombinant DNA and vectors according to the present invention may be made as follows. A suitable vector containing the desired base sequence for transcription (for example pTOM5) is  
5 treated with restriction enzymes to cut the sequence out. The DNA strand so obtained is cloned (if desired, in reverse orientation) into a second vector containing the desired promoter sequence, for example cauliflower mosaic virus 35S promoter  
10 or the tomato polygalacturonase gene promoter sequence - Bird et al., Plant Molecular Biology, 11, 651-662, 1988) and the desired terminator sequence (for example the 3' of the Agrobacterium tumefaciens nopaline synthase gene, the nos 3'  
15 end).

According to the invention we propose to use both constitutive promoters (such as cauliflower mosaic virus 35S) and inducible or developmentally regulated promoters (such as the ripe-fruit  
20 specific polygalacturonase promoter) as circumstances require. Use of a constitutive promoter will tend to affect functions in all parts of the plant: while by using a tissue-specific promoter, functions may be controlled more  
25 selectively. Thus in applying the invention, e.g. to tomatoes, it may be found convenient to use the promoter of the PG gene (Bird et al, 1988, cited above). Use of this promoter, at least in tomatoes, has the advantage that the production of  
30 recombinant RNA is under the control of a ripening-specific promoter. Thus the recombinant RNA is only produced in the organ in which its action is required. By this means particular organs can have their colour modified. For plants to be used as ornament (as many are), by using a constitutive promoter one may induce carotenoid production

**SUBSTITUTE SHEET**

- 11 -

throughout the plant to provide plants with an overall modified or reddish/yellowish colour: normally it will be preferred to limit the production to particular sites (such as fruit,  
5 flower petals or tubers) by using a tissue-specific or developmentally regulated promoter, for example the PG gene promoter referred to above. Other ripening-specific promoters that could be used include the E8 promoter (Diekman & Fischer, EMBO  
10 Journal 7, 3315-3320, 1988) and the 2A11 promoter from tomatoes described in US Patent 4,943,674 to Calgene.

Vectors according to the invention may be used to transform plants as desired, to make plants  
15 according to the invention. Dicotyledonous plants, such as tomato, may be transformed by Agrobacterium Ti plasmid technology, for example as described by Bevan (1984) Nucleic Acid Research, 12, 8711-8721. Such transformed plants may be reproduced sexually,  
20 or by cell or tissue culture.

The degree of production of RNA in the plant cells can be controlled by suitable choice of promoter sequences, or by selecting the number of copies, or the site of integration, of the DNA  
25 sequences according to the invention that are introduced into the plant genome. In this way it may be possible to modify colour formation to a greater or lesser extent.

The constructs of our invention may be used to  
30 transform cells of both monocotyledonous and dicotyledonous plants in various ways known to the art. In many cases such plant cells (particularly when they are cells of dicotyledonous plants) may be cultured to regenerate whole plants which subsequently reproduce to give successive generations of genetically modified plants.

- 12 -

Examples of genetically modified plants according to the present invention include, as well as tomatoes, fruits of such as mangoes, peaches, apples, pears, strawberries, bananas and melons.

5 The fruit of such plants may be made more attractive (or at least interesting) by inducing or intensifying a red colour therein. Other plants that may be modified by the process of the invention include tubers such as radishes, turnips  
10 and potatoes, as well as cereals such as maize (corn), wheat, barley and rice. Flowers of modified colour, and ornamental grasses either red or reddish overall, or having red seedheads, may be produced.

15 Plants produced by the process of the invention may also contain other recombinant constructs, for example constructs having other effects on fruit ripening. In particular tomatoes of enhanced colour according to the invention may  
20 also contain constructs inhibiting the production of enzymes such as polygalacturonase and pectinesterase, or interfering with ethylene production (eg from pTOM13, see PCT Application 90/01072 filed 12 July 1990). Such tomatoes can  
25 have higher solids contents than conventional tomatoes and produce more tomato paste per unit of fruit weight. The extra lycopene production in such tomatoes is desirable to prevent any lightening of colour that might otherwise be  
30 observed in such pastes. Tomatoes containing both types of recombinant construct may be made either by successive transformations, or by crossing two varieties that each contain one of the constructs, and selecting among the progeny for those that contain both.

The invention will now be described further

5            Figure 2 shows the regions of the pTOM5 sequence which may be synthesised by polymerase chain reaction and used in the construction of vectors according to the invention;

Figure 4 is a diagram of the carotenoid synthesis pathway;

Figure 6 is a diagram of DNA vector pCB19;

20            Figure 8 diagrams the scheme for the  
             manufacture of construct pCBEX5.

25                   EXAMPLE 1

Construction of pTOM5 antisense RNA vectors with  
the CaMV 35S promoter

Three vectors may be constructed using  
sequences corresponding to different lengths of the  
30 pTOM5 cDNA as shown in figure 2.

1. bases 1 to 187 - pJR15A
2. bases 1 to 794 - pJR15B
3. bases 1 to 1598 ( the complete cDNA) - pJR15C

- 14 -

pJR15B was synthesised in vitro using polymerase chain reactions with synthetic oligonucleotides T5AS-1 and T5AS-3 shown in Figure 2 as primers and pTOM5 cDNA as template. The  
5 synthetic oligo nucleotide primers were designed such that a BamHI restriction site was incorporated at the 5' end a KpnI site was incorporated at the 3' end of the fragment. After cleavage with BamHI and KpnI, the fragment was cloned into the vector  
10 pJR1 which had previously been cut with KpnI and BamHI. pJR1 (Smith et al Nature 334, 724-726, 1988) is a Bin19 ( Bevan, Nucleic Acids Research, 12, 8711-8721, 1984) based vector, which permits the expression of the antisense RNA under the  
15 control of the CaMV 35S promoter. This vector includes a nopaline synthase (nos) 3' end termination sequence.

After synthesis of the vector pJR15B, the structures and orientation of the pTOM5 sequence  
20 was confirmed by DNA sequence analysis.

Vectors pJR15A and pJR15C are made similarly, following the construction schemes shown in Figures 2 and 3.

## 25 EXAMPLE 2

Construction of pTOM5 antisense RNA vectors with the polygalacturonase promoter.

The fragments of the pTOM5 cDNA described in Example 1 are also cloned into the vector pJR2 to  
30 give the following clones:

- |                    |          |
|--------------------|----------|
| 1. bases 1 to 187  | - pJR25A |
| 2. bases 1 to 794  | - pJR25B |
| 3. bases 1 to 1598 | - pJR25C |

- 15 -

pJR2 is a Bin19 based vector, which permits the expression of the antisense RNA under the control of the tomato polygalacturonase promoter. This vector includes a nopaline synthase (nos) 3' end termination sequence. This vector does not contain a KpnI or a BamHI site between the promoter and terminator sequences. Consequently, the PCR synthesised fragments are digested with KpnI and BamHI, the cut ends are made flush with T4 polymerase and then cloned into the HincII site of pJR2

After synthesis, vectors with the correct orientation of pTOM5 sequence are identified by DNA sequence analysis.

#### 15 EXAMPLE 3

Construction of pTOM5 sense RNA vectors with the CaMV 35S promoter

The fragments of pTOM5 cDNA described in Example 2 are also cloned into the vector pJR1 in the sense orientation to give the following clones:

1. bases 1 to 187 - pJR15AS
2. bases 1 to 794 - pJR15BS
3. bases 1 to 1598 - pJR15CS

The PCR generated fragments are digested with KpnI and BamHI, the cut ends made flush with T4 polymerase and then cloned into the HincII site of pJR1. After synthesis, the vectors with the sense orientation of pTOM5 sequence are identified by DNA sequence analysis.

#### EXAMPLE 4

Generation and analysis of plants transformed with the vector pJR15B.

The pJR15B vector was transferred to Agrobacterium tumefaciens LBA4404 (a micro-organism

**SUBSTITUTE SHEET**

- 16 -

widely available to plant biotechnologists) and used to transform tomato plants. Transformation of tomato stem segments followed standard protocols (e.g. Bird et al Plant Molecular Biology 11, 651-662, 1988). Transformed plants were identified by their ability to grow on media containing the antibiotic kanamycin. Forty-one individual plants were regenerated and grown to maturity.

Thirty-seven of these plants produced fruit which changed colour to yellow rather than to red: they did not turn red even when over-ripe. Fruit from the other four plants turned orange-red.

The flowers of plants with yellow fruit had pale corollae. The accumulation of yellow pigment in flowers varied between individual transformants with some flowers being almost white.

Preliminary analysis indicated that carotenoid accumulation in the yellow fruit was approximately 6% of that in untransformed controls. Almost no lycopene was detected (<2% of that in normal fruit): the majority of residual carotenoid was lutein and  $\beta$ -carotene, neither of which accumulated to significantly greater levels than in the control fruit. Most of the yellow fruit pigment was in the skin, and could not be extracted by methanol. Thus it is unlikely to be carotenoid.

Three of the transformants giving yellow fruit and two of the transformants giving red fruit were submitted to polymerase chain reaction analysis. This indicated that the pJR15B antisense construct was present and intact in all five. DNA blot analysis indicated that the insert copy number was between 1 and 4.

One transformed plant, coded E64C8, with yellow fruit, was selfed to produce progeny. These showed segregation of yellow and white flower

**SUBSTITUTE SHEET**

- 17 -

colour according to Mendelian principles,  
indicating that the plant contains one functional  
copy of the antisense construct, and that the  
phenotype is stably inherited.

5

## EXAMPLE 5

Construction of pTOM5 expression vectors with  
the CaMV 35S promoter.

Construction of pJREX5

10 The expression vector pJREX5 is synthesised in  
vitro according to the scheme shown in Figure 7.  
The 1468 bp SspI fragment is isolated from pTOM5,  
the cut ends are made flush with T4 polymerase and  
the resulting product is then cloned into the SmaI  
15 site of the plasmid pJR1.

After synthesis, vectors with sense and  
antisense orientation of the pTOM5 fragment are  
identified by DNA sequence analysis.

20

## EXAMPLE 6

Construction of pTOM5 expression vectors with  
the tomato polygalacturonase promoter.

A. Construction of pCB17.

25 A 1.6 kb region from the 3' end of the tomato  
PG gene was substituted for the nopaline synthase  
polyadenylation sequence in pCB1 (Bird et al Plant  
Molecular Biology 11, 651-662, 1988).

30 The 5.8 kb SalI/BamHI fragment adjacent to the  
right arm of lambda EMBL3 in gTOM23 was cloned into  
the SalI/BamHI sites of pUC8 to give plasmid  
pGTOM23.5.8. The 1.6 kb BgIII fragment from  
pGTOM23.5.8 was isolated and cloned into the BamHI  
site of pUC19. Plasmids with the correct  
orientation of the 1.6 kb BgIII insert contained a  
550 bp XbaI/BstEII fragment. One such clone was  
designated A3/1.

SUBSTITUTE SHEET

- 18 -

A 2.2 kb HindIII/PvuI was isolated as a fragment from pCB1. This contained a 1.45kb PG promoter fragment and the chloramphenicol acetyl transferase (CAT) gene. This was cloned into Bin19 (Bevan, Nucleic Acids Research, 1984, 12, 8711-8721) which had been cut with SalI followed by filling of the cohesive ends with T4 DNA polymerase and subsequently digested with HindIII. Plasmids with the 2.2 kb HindIII/PvuI fragment contained a 2.2 kb HindIII/XbaI fragment. One of these clones was digested with XbaI and KpnI and ligated with the 1.6 kb XbaI/KpnI fragment from A3/1. After transformation, one clone with the correct insert was designated pCB17 (Figure 5).

The correct construction of pCB17 was checked by nucleotide sequence analysis of the plasmid DNA at the boundary between the CAT gene and the PG 3' fragment. An unexpected region of the Bin19 polylinker was found to have remained at this junction. This was judged to be unlikely to interfere with the correct functioning of the plasmid. The sequence of pCB17 in this region is:

25	CAT	BIN19 POLYLINKER	PG 3'
	...CCGTCCCCGTGCATGCCTGCAGGTCGACTCTAGAGGATCTTCAATATA		
	TAG...	XbaI	

#### B. Construction of pCB19

The PG promoter region in plasmid pCB17 was extended by the addition of a 3.5 kb fragment from genomic clone gTOM23 (NCIMB Accession Number 12373).

The 3.5 kb HindIII fragment from pGTOM23.7.8 was cloned into the HindIII site in pCB17. Plasmids with the correct orientation of the 3.5 kb

**SUBSTITUTE SHEET**

- 19 -

Hind AYE insert contained a 4.9 kb SaII/BamI fragment. One such clone was designated pCB19 (Figure 6).

5 C. Construction of pCB19

The expression vector pCBEX5 is synthesised in vitro according to the scheme shown in Figure 8. The 1468 bp SspI fragment is isolated from pTOM5, and the cut ends are made flush with T4 polymerase. 10 The resulting product is then cloned into pCB19 from which the BamHI - XbaI fragment encoding chloramphenicol acetyl transferase has been deleted and the cut ends made flush with T4 polymerase.

After synthesis, vectors with sense and 15 antisense orientation of the pTOM5 fragment are identified by DNA sequence analysis.

EXAMPLE 7

Generation of transformed plants with the 20 sense vectors pJREX5 and pCBEX5. The required sense expression vector (produced in Example 5 or 6) is transferred to Agrobacterium tumefaciens LBA4404 (a micro-organism widely available to plant biotechnologists) and used to 25 transform tomato plants. Transformation of tomato stem segments follow standard protocols (e.g. Bird et al Plant Molecular Biology 11, 651-662, 1988). Transformed plants were identified by their ability to grow on media containing the antibiotic 30 kanamycin and by the detection of DNA by DNA blot analysis of their genomic DNA. Ripening fruit are analysed for levels of lycopene and other carotenoids. Plants with higher than normal lycopene levels are selected for further use and study.

## CLAIMS:

1. DNA constructs comprising a DNA sequence showing homology to at least some of the gene for the gene product encoded by the clone pTOM5, preceded by a transcriptional initiation region  
5 operative in plants, so that the construct can generate mRNA in plant cells.
2. DNA constructs as claimed in claim 1 comprising a transcriptional initiation region  
10 operative in plants positioned for transcription of a DNA sequence encoding RNA complementary to a base sequence showing substantial homology to an mRNA encoding the enzyme produced by the gene of pTOM 5.
- 15 3. DNA constructs as claimed in claim 1 comprising a transcriptional initiation region operative in plants positioned for transcription of a DNA sequence to give mRNA which can be translated to give the enzyme produced by the gene of pTOM 5.  
20
4. DNA constructs as claimed in claim 1 comprising a transcriptional initiation region operative in plants positioned for transcription of a DNA sequence encoding RNA showing substantial  
25 homology to part only of the mRNA encoding the enzyme produced by the gene of pTOM 5.
5. DNA constructs as claimed in any of claims 1 to 4 in which the transcriptional initiation region  
30 is a constitutive promoter such as CaMV 35S.
6. DNA constructs as claimed in any of claims 1 to 5 in which the transcriptional initiation region is an inducible or developmentally-regulated or

SUBSTITUTE SHEET

- 21 -

tissue-specific promoter.

5

7. A process for modifying the production of carotenoids in plants by transforming such plants with DNA adapted to modify carotenoid biosynthesis and growing such transformed plants or their  
10 descendants to produce plant parts of modified carotenoid content.

15

8. Process as claimed in claim 7 in which the DNA is a construct claimed in any of claims 1 to 6.

9. A process for producing plants having parts of modified colour which comprises transforming plants with DNA adapted to modify production of lycopene therein and growing such transformed plants or  
20 their descendants to produce plant parts of changed colour.

10. Process as claimed in claim 9 in which the plant naturally produces lycopene and the construct  
25 is adapted to inhibit the production of lycopene.

11. Process as claimed in claim 10 in which the DNA construct is one claimed in either of claims 2 or 4.

30

12. Process as claimed in claim 9 for producing or intensifying a red colour in plant parts in which the construct is adapted to promote the construction of lycopene.

13. Process as claimed in any of claims 10 to 12 in which the construct is one claimed in claim 3.

**SUBSTITUTE SHEET**

- 22 -

- 5 14. Process as claimed in any of claims 7-13 in which the plant is a tomato.
15. Transformed plants produced in the processes of any of claims 7-13.
- 10 16. Plants as claimed in claim 15 which are fruit, eg tomatoes, mangoes, peaches, apples, pears, strawberries, bananas, melons or citrus fruit.
- 15 17. Plants as claimed in claim 15 which are tubers such as radishes, turnips and potatoes.
- 20 18. Plants as claimed in claim 15 which are cereals such as maize (corn), wheat, barley and rice.
19. Plants as claimed in claim 15 that are ornamental in function, e.g. flowers.
- 25 20. Plant parts of modified colour harvested from plants claimed in any of claims 15-19.
- 30 21. Fruit and seed of plants claimed in any of claims 15-19.
22. A tomato as claimed in claim 14 which additionally comprises a recombinant construct inhibiting the production of polygalacturonase or pectinmethylesterase.

## FIG. 1

SEQ ID NO: 1  
SEQUENCE TYPE: Nucleotide  
SEQUENCE LENGTH: 1646 base pairs

STRANDEDNESS: single  
TOPOLOGY: linear  
MOLECULE TYPE: cDNA

ORIGINAL SOURCE ORGANISM: Tomato var. Ailsa Craig  
IMMEDIATE EXPERIMENTAL SOURCE: Ripe fruit cDNA library

FEATURES:  
from 201 to 1436 bp open reading frame

PROPERTIES: cDNA of tomato fruit ripening related gene - pTOM5
